Who Are We Looking At

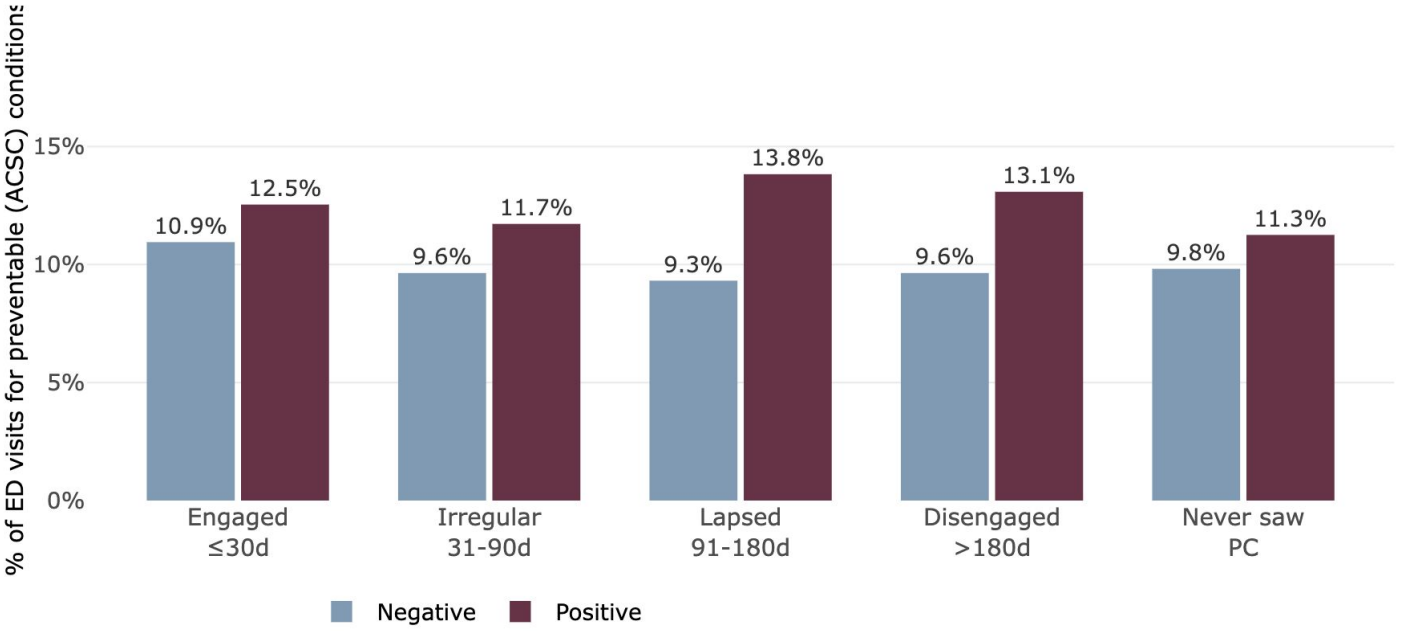

Care Continuity, Not Crisis Response

ACSC: ambulatory care sensitive conditions

Does the gap predict preventable visits?

Positive screeners have more preventable ED visits at every level of primary care engagement — even patients seen within the last 30 days.

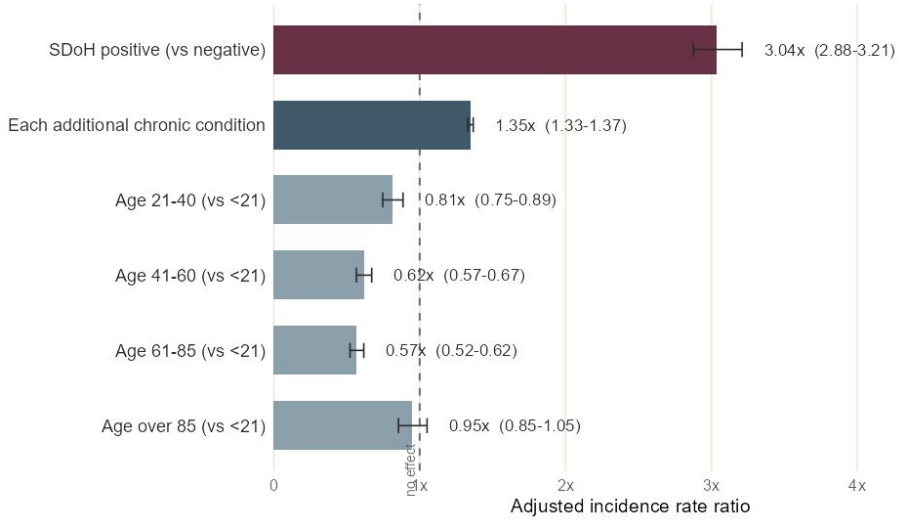

Adjusting for Age and Comorbidity

After adjusting for age and comorbidity, Financial Resource Strain-positive patients have **3.04x** the ED visit rate of negative screeners (95% CI: 2.88-3.21).

Adjusted incidence rate ratios

Negative binomial regression. Outcome is total ED visits, with log(years observed) as offset.

Bars show adjusted IRRs from negative binomial regression. Black whiskers show 95% confidence intervals. Bars to the right of 1x indicate

3.04x more ED visits

Even after adjusting for age and chronic disease, patients with financial strain use the emergency department three times as often as patients without.

The effect is larger than any age group or chronic condition.
